

The image features several groups of simple stick figures in light gray. On the left, a group of about seven figures stands together. In the center, a single figure stands with arms raised. To the right of the center, three figures are walking. On the far right, a larger group of about ten figures is gathered, some with arms raised. The text "All for one or some for all" is overlaid on the scene, with the underlined portion positioned over the three walking figures.

# Introduction: Bayes factors

- So far, focus on **estimation**, but what if you want to test hypotheses?
- Null hypothesis significance testing
  - $H_0: \theta_1 = \theta_2 = \theta_3$  vs  $H_a: \text{not } \theta_1 = \theta_2 = \theta_3$
  - p-value to reject  $H_0$  or not
  - Not possible to compare specific hypotheses
- Bayes factor!

# Introduction: Bayes factors

- Bayesian version of hypothesis testing
- $BF_{ab}$  compares any two hypotheses

$$H_0: \theta_1 = \theta_2 = \theta_3$$

$H_a$ : not  $H_0$

# Introduction: Bayes factors

- Bayesian version of hypothesis testing
- $BF_{ab}$  compares any two hypotheses

$$H_0: \theta_1 = \theta_2 = \theta_3$$

$H_a$ : not  $H_0$

$$H_1: \theta_1 > \theta_2 > \theta_3$$

$$H_2: \theta_1 > \theta_3 > \theta_2$$

$H_3$ : not  $H_1$  or  $H_2$

$$H_4: \theta_1 = \theta_2 > \theta_3$$

# Introduction: Bayes factors

- How does it work?

$$\frac{\Pr(D|M_1)}{\Pr(D|M_2)} = \frac{\int \Pr(\theta_1|M_1) \Pr(D|\theta_1, M_1) d\theta_1}{\int \Pr(\theta_2|M_2) \Pr(D|\theta_2, M_2) d\theta_2}$$

- Balance complexity and fit

- $\text{BF}_{i0} = \frac{\textit{fit}_i}{\textit{complexity}_i}$

# Introduction: Bayes factors

- Bayes factor expresses the support the data for  $H_a$ , relative to  $H_b$ 
  - $BF_{ab} = 5$ ,  $H_a$  is 5 times more likely than  $H_b$
  - $BF_{ab} = .1$ ,  $H_b$  is 10 times more likely than  $H_a$
- Possible to compare multiple hypotheses

## All for one or some for all? Evaluating informative hypotheses using multiple $N = 1$ studies

**Abstract** Analyses are mostly executed at the population level, whereas in many applications the interest is on the individual level instead of the population level. In this paper, multiple  $N = 1$  experiments are considered, where participants perform multiple trials with a dichotomous outcome in various conditions. Expectations with respect to the performance of participants can be translated into so-called informative hypotheses. These hypotheses can be evaluated for each participant separately using Bayes factors. A Bayes factor expresses the relative evidence for two

individuals. Two additional measures are proposed to support the interpretation of the gP-BF: the evidence rate (ER), the proportion of individual Bayes factors that support the same hypothesis as the gP-BF, and the stability rate (SR), the proportion of individual Bayes factors that express a stronger support than the gP-BF. These three statistics can be used to determine the relative support in the data for the informative hypotheses entertained. Software is available that can be used to execute the approach proposed in this paper and to determine the sensitivity of the outcomes with
